

# sequential memory-hard key derivation with better measurable security

caveman

January 1, 2021

## Abstract

hi — i propose *ciphart*, a sequential memory-hard key derivation function that has a security gain that's measurable more objectively and more conveniently than anything in class known to date.

to nail this goal, *ciphart*'s security gain is measured in the unit of *relative entropy bits*. relative to what? relative to the encryption algorithm that's used later on. therefore, this *relative entropy bits* measure is guaranteed to be true when the encryption algorithm that's used with *ciphart* is also the same one that's used to encrypt the data afterwards.

my reference implementation is available here:

## 1 ciphart

**input:**  $b$  number of entropy bits to be added.  
 $m_t$  memory pad of  $t^{th}$  task, at least 32 bytes.  
initialised to some constant value.  
 $m_t[0 : 16]$  means first 16 bytes.  
 $m_t[-16 : ]$  means last 16 bytes.  
 $R$  number of rounds per task.  
 $e$  encryption function.  
 $k$  initial key.  
**output:**  $\hat{k}$  better key.

```
1: define  $P$  and  $T$  such that  $PTR - 2^b$  is smallest  
   positive number,  $P \geq 2$ ,  $T$  is an even number.  
2:  $x \leftarrow 0$  is a 16 bytes wide variable.  
3: for  $p = 1, 2, \dots, P$  do  
4:   for  $t = 1, 3, \dots, T - 1$ , in steps of 2 do  
5:      $a \leftarrow t$   
6:      $b \leftarrow t + 1$   
7:     for  $r = 1, 2, \dots, 2R$  do  
8:        $n \leftarrow (p, t, r)$   
9:        $m_a \leftarrow e(m_b, k, n)$   
10:       $\hat{a} \leftarrow a$   
11:       $a \leftarrow b$   
12:       $b \leftarrow \hat{a}$   
13:    end for  
14:     $x \leftarrow x \oplus m_a[-16 : ]$   
15:     $x \leftarrow x \oplus m_b[-16 : ]$   
16:  end for  
17:  for  $t = 1, 2, \dots, T$  do  
18:     $m_t[0 : 16] \leftarrow m_t[0 : 16] \oplus x$   
19:  end for  
20: end for  
21: return  $\hat{k} \leftarrow \text{hash}(m_1, m_2, \dots, m_T)$ 
```
